ABSTRACT

Background: Nocturnal enuresis or bedwetting is a common health problem in children in the age group of 5 to 15 years. In India the prevalence of nocturnal enuresis ranges from approximately 7% to 12.6%. The prevalence from other parts of the world ranges from 6% to 42%. This study was planned to find the prevalence and determinants of nocturnal enuresis in school going children.

Methods: This cross-sectional study was conducted in four primary and secondary schools in Solapur. A predefined questionnaire, prepared in English and translated to local languages, Marathi and Kannada, was handed over to all the children attending the selected schools. Children were asked to hand over the questionnaire to their parents and return with the filled questionnaire. The questionnaire was prepared to obtain the information related to the socio-demographic factors of the family and child, frequency of enuresis and information related the risk factors. Nocturnal enuresis was defined if the frequency of enuresis was more than twice per week.

Results: The overall prevalence of nocturnal enuresis was 11.4 %. The maximum prevalence was found in the age group of 8 -9 years (22.96 %). The prevalence of nocturnal enuresis in boys (14.34 %) was significantly more than the prevalence in girls (8.31 %). The study showed that nocturnal enuresis was significantly associated with stress, poor school performance, sleep pattern (hard to awaken), family history, burning micturition etc. But it was not associated with maternal or paternal education, birth order, type of family.

Conclusions: The prevalence of nocturnal enuresis is 11.40 % in school going children and it is associated with age, sex, stress, family history, burning micturition, hyperactive child, poor school performance, sleep pattern (hard to awake) avoidance of going to micturate before sleep etc.

Keywords: Burning micrturition, Nocturnal enuresis, School going children, Sleep pattern

INTRODUCTION

Nocturnal enuresis or bedwetting is a common health problem in children in the age group of 5 to 15 years. It is defined as an involuntary voiding of urine during sleep with a frequency of at least twice a week in children aged ≥5 years in the absence of congenital or acquired defects of the central nervous system.¹ The available data from India shows that the prevalence of nocturnal enuresis ranges from approximately 7% to 12.6%.²⁻⁵ The prevalence from other parts of the world ranges from 6 % to 42 %.⁶⁻¹³

Enuresis can be nocturnal or daytime enuresis. It can also be primary or secondary. There are many possible causes of nocturnal enuresis including anxiety, hyperactivity...
disorder, a gene located on chromosome 12q, overactive bladder, urinary tract infection, antidiuretic hormone deficiency, diabetes, small bladder, constipation etc. The data also suggest that the annual spontaneous resolution rate is approximately 15 to 16%.

Nocturnal enuresis is a common problem which causes psychological trauma to the child as well as to the family which can result in social avoidance, feeling of guilt and shame, loss of self-esteem and can result in overall psychological development of the child.

There are numerous factors associated with the nocturnal enuresis. Few of the associated factors are sex, stress, parental education, school performance, sleep pattern etc.

The studies on prevalence and risk factors for nocturnal enuresis not conducted in rural part of Maharashtra. So, to fill of this gap in available literature, this study was planned to find the prevalence and determinants of nocturnal enuresis in school going children.

**METHODS**

This cross-sectional study was conducted by department of Paediatrics, Ashiwni Rural Medical College, Hospital and Research Centre, Solapur. The study period was July 2018 to August 2018. The study was conducted in four primary and secondary schools in Solapur. Two of them were Marathi medium schools and two were English medium schools.

**Inclusion criteria**

- School going child in the age group of 5 to 15 years.
- Child and parents ready to participate in the study and responded to the questionnaire.

**Exclusion criteria**

- Child below the age of 5 years and above 15 years
- Did not respond to the questionnaire.

A predefined questionnaire, prepared in English and translated to local languages, Marathi and Kannada, was handed over to all the children attending the selected schools. Children were asked to hand over the questionnaire to their parents and return with the filled questionnaire.

The questionnaire was prepared to obtain the information related to the socio-demographic factors of the family, information related to child’s age, sex and other factors, frequency of enuresis and information related the risk factors.

The required sample size was calculated by considering the prevalence of nocturnal enuresis as 12.6 % as reported by a study conducted amongst the school going children in Lucknow. With alpha=0.05 and allowable relative error of 10 %, the calculated required sample size was 1360, to estimate the prevalence within 10 % relative error. Nocturnal enuresis was defined if the frequency of enuresis was more than twice per week 17.

Nocturnal enuresis was defined as secondary, if the child had attained full control over his nocturnal bladder habits for a continuous period of at least six months. Otherwise the nocturnal enuresis was defined as primary.

**Statistical analysis**

Univariate analysis was done using appropriate statistical tests like chi-square test, t test etc. Data was analysed using SPSS 23.

**RESULTS**

The total number of questionnaires distributed were 1710 in the selected four schools. Out of these 1710 questionnaire distributed, only 1430 completely filled questionnaire were returned.

So, the response rate was 83.63%. Out of that 657 were from Marathi medium schools and 773 were from English medium schools.

The response rate from English medium schools (87.64 %) was better than the response rate from Marathi Medium schools (79.35 %). The overall prevalence of nocturnal enuresis was 11.4 %. The maximum prevalence was found in the age group of 8-9 years (22.96 %). The prevalence of nocturnal enuresis in the age group of 7-8 was 18.92 %. There was only one child suffering from nocturnal enuresis in the age group of 13-14, whereas no child complained of it above the age of 14 years (Table 1). The differences in the prevalence rates in these age groups were statistically significant. (χ²= 77.65, p = 4.15 x 10⁻⁵). The prevalence of nocturnal enuresis in boys (14.34 %) was significantly more than the prevalence in girls (8.31 %). The odds ratio was 1.85 (95 % confidence interval-1.32-2.59) (Table 2). The prevalence of nocturnal enuresis was more in Marathi medium school as compared with English medium school (Table 3).

Table 4 shows the association of nocturnal enuresis with various socio-demographic and other factors. It shows that the nocturnal enuresis was significantly associated with socio-economic status, stress, poor school performance, sleep pattern (hard to awaken), family history, burning micturition, not going to toilet before bed. But it was not associated with maternal or paternal education, birth order, type of family. A total of 102 (62.58 %) children’s parent felt that it was an abnormal condition and consulted any doctor. Remaining 61 parents felt that the nocturnal enuresis or bedwetting is a common and normal phenomenon.

DISCUSSION

The present cross-sectional study was conducted in school going children in the age group of 5 to 15 years to estimate the prevalence of nocturnal enuresis and its
The present study has also revealed different prevalence rate as reported by various authors from different regions of the world. The prevalence of nocturnal enuresis in this study was lower than the reported studies from Stephanie Gonzalez Mejias and Kamleshun Ramphul (Dominican Republic, 27.9%), Aloni MN et al (Congo, 26%), Iduoriyekemwen NJ et al (Nigeria 21.3%), Bourquia A (Morocco, 35.0%), Järvelin MR (Finland 8.2%), Readett DR (Jamaica 50%). However, it was higher than a study from Hansakunachai T et al (Bangkok 3.9%). The differences in the age groups and different socio-demographic characteristics were the main reasons in these different prevalence rates. The study has shown that the prevalence was more in the age group of 7-9 years. The findings are similar to the findings of Aljefri HM, De Sousa et al and Srivastava S et al. The study has also reported that with advancing age, the prevalence decreased. The findings of the study, boys are more affected than girls, are also similar to the findings of De Sousa et al, Mithani S et al, Ozden C et al, Pashpour et al. However, the results were not consistent with reports of Yousef KA and Aljefri HM.

CONCLUSION

Nevertheless, the study has concluded that the prevalence of nocturnal enuresis is 11.40% in school going children and it is associated with age, sex, stress, family history, burning micturition, poor social performance, sleep pattern (hard to awake) avoidance of going to micturate before sleep etc. It has also pointed out that the nocturnal enuresis was not associated with maternal or paternal education, birth order or type of family.
